INTRODUCTION

The Fossil Fish Collection belongs to the “Palaeozoology: Vertebrates” subdivision of the palaeontology collection of the State Museum of Natural History NAS of Ukraine (further SMNH). It was distinguished during the latest inventory check up of the museum collections which took place between 1997 and 2007 (Voichyshyn 2009). The collection included all fish fossil remains kept in the museum except the shark teeth. Presently, Fossil Fish Collection contains 1562 specimens (units of storage). In its core there is a set of the remains of the Devonian vertebrate fauna, which represents 87% of the entire collection and is the scope of the present publication.

The Devonian part of the Fossil Fish Collection is composed principally of material from Podolia. Aside from the Podolian specimens, the collection contains fragments of the exoskeleton of the Middle and Late Devonian armoured fishes from the Swietokrzyskie Mountains (Poland).

The main part of the Devonian fish fauna set from Podolia (more than 90%) consists of the remains of the jawless fishes (Agnatha) from the subclasses Heterostraci and Osteostraci (Fig.1). The fishes proper, classes Placodermi and Acanthodii, in contrast with the agnathans, are insignificantly represented in the collection. In case of the acanthodians the reason is that they had for the most part small size. Furthermore their exoskeleton usually disintegrated into separate scales, dermal bone platelets etc after an animal death while the collection was completed with fossil macroremains only until recent times. For this reason all of the Podolian thelodont and chondrichthyan species are lacking in the collection list of taxa as well. At the same time, shares of the more numerous Early Devonian fish fauna high taxa within Fossil Fish Collection (Heterostraci, Osteostraci and Placodermi) roughly reflect their quotas in the Podolian fossil assemblages.

The oldest documented findings of the Devonian fish fauna of Podolia in the museum collection are a few specimens that were collected at the end of the 19th century by the Polish archaeologist Gotfryd Ossowski (1835-1897) and the well-known Galician naturalist Marian Łomnicki (1845-1915) who eventually became a curator of the Zoology department in the Dzieduszycki Museum (present SMNH). A small number of the specimens were received from the Museum of the Shevchenko Scientific Society in 1940. The L'viv University professor Władysław Zych (1899-1981) collected over a thousand specimens of the fossil agnathans and fishes in Podolia at least between 1924 and 1940 as documented with labels. After World War II a part of his collection stayed at the Geology Faculty, and after the petition of Dr. Pavlo Balabai (1904-1961) was transferred for storage at the Scientific Nature Museum AS UkrSSR (present SMNH). Zych's collection makes up fifth of the current collection of the Devonian fish fauna. Some materials were collected during the search parties of the All-Union Oil Scientific Research Exploration Institute between 1948 and 1950. About 10% of the collection was gathered between 1948 and 1960 by Dr. Balabai and other contemporary collectors (S. Kotsiubyns'kyi, L. Opalatenko, V. Havrylyshyn etc). The next period of the material substantial replenishment takes place between 1986 and 2006 when the collection almost doubled in size thanking to the field work of V. Voichyshyn, D. Drygant, S. Solodkyi et al.

Among the Podolian material collectors were a founder of the Stockholm school of Palaeozoology Professor Erik Stensiö (1891-1984), Soviet geologists, professors Grigory Dickenstein (1911-1990) and Vladimir Tikhomirov (1915-1994), and other scientists. The

armoured fish remains from the Swietokrzyskie Mountains were collected by Polish geologists Jan Czarnocki (1889-1951) and Tadeusz Dybczynski (1886-1944). In general there are 35 collectors known to be responsible for the 92% of the collection materials although not all of these persons are completely identified. For the rest 8% no information concerning collector name is known.

According to the literary (Voichyshyn 2001a, 2011) and the collection labels data, 100 localities of the fish fossil remains of Podolian Early Devonian basin are known up-to-date, whereas the museum collection contains fish fossils only from about half of them (Fig. 4). The bulk of the fossil material (one third of total amount of the specimens) comes from environs of Ustechko village which can be considered as the richest locality of Early Devonian vertebrate remains in Podolia. This estimate owes particularly to wide stratigraphical range of the locality exposures, from uppers of the Ivanie Formation of the Tyver Group to lower part of the Khmeleva Stage of the Dniester Formation. At the same time, this range corresponds to the period when taxonomical diversity of Podolian fish fauna reached peak of its value (Voichyshyn 2014). Besides, the facial conditions of deposit formation during this time were the most suitable for burial of the fish remains within all Early Devonian fish fauna history in Podolia (Voichyshyn 1998a, 2011). The second in fish fossil abundance within the collection localities list is Yagilnytsia Stara due to dozen of small heterostracan shields which were found here (Voichyshyn 1997). The credit for the discovery and exploration of this locality is given to W. Zych. Although all his collection from this site was dated 1934, he published some material with Yagilnytsia Stara origin as early as 1931 (Zych 1931). It seems that later no one found anything there. My attempts to find the location in 1988 were not crowned with success. Horodnytsia is the third in the collection range of Podolian fossil-rich localities. Fossils abundance here has been caused in part by presence of developed system of quarries in Levets' River valley in the environs of this village. Ustechko, Yagilnytsia Stara and Horodnytsia together are places of origin of more than half of the collection specimens (Fig. 2).

The fish-bearing deposits which represented in the Podolian part of the collection relate to the local stratigraphy scheme of the Lochkovian time as follows: sublittoral deposits correspond to the Chortkiv Formation, littoral deposits relate with the Ivanie Formation, and terrigenous deposits belong to the Ikva Group (see Voichyshyn 2011). Terrigenous deposits of the Pragian time fall within the Dniester Formation. Taking into account long time collecting only fossil macroremains it is not surprising that three fifth of the collection specimens related to the terrigenous deposits of the Pragian time (Fig. 3) which are represented by the multitude of localities.

There are three main fossil-bearing horizons (levels) in the Ustechko locality mentioned in the catalogue. All of them situate at the main outcrop westward the village, on the left bank slope of the Dniester River. The first horizon, named "level Z", can be found about one metre above the road level from the beginning of the outcrop to the destroyed bridge. It corresponds with approximately the boundary between the Ustechko and the Khmeleva Stages of the Dniester Formation. The second fossil-bearing horizon, named "level Zsc" (after *Zascinaspis heintzi*, the horizon most numerous species), is about 15 metres above the first one and comes to light in the beginning of the outcrop and in the ravines before it. The third horizon, named "level P", is about 20 metres above the water level and manifests itself in the western part of the outcrop, beyond the destroyed bridge.

Fig. 5. Outcrops along the Dniester River where fish fossil microremains of SMNH collection were sampled (after Drygant 2010: fig. 1.8, modified).

Both the second and the third horizons correlate with the lower part of the Khmeleva Stage of the Dniester Formation.

Collection material was represented till recently by macroremains of the fish fauna, i.e. by relatively large (from several centimetres to one and half decimetre in length) armours, separated plates, shields, and their moulds or imprints in rock. Nonetheless, Fossil Fish Collection has been enriched with 250 microremains (18 units of storage) of Early Devonian fish fauna in 2008. The microremains are tiny (from tenth millimetre to a few millimetres) fragments of fossil fish armour as well as their scales or tesserae. These specimens were obtained via dissolving of limestone rocks collected between 1966 and 2004 by Dr. Daniel Drygant (SMNH) and between 1999 and 2004 by Prof. Andrzej Bałiński (Institute of Paleobiology of the Polish Academy of Sciences, Warszawa) from marine deposits of Podolian Lower Devonian section in the Dniester River valley (Fig. 5). The collection has yet 13 microremains (6 units of storage) of *Zascinaspis ?heintzi* and an undescribed osteostracan species exoskeleton from the terrigenous deposits of Lower Devonian of Podolia.

The Devonian jawless fish set contains the type material concerning the following species: *Alaeckaspis ustetchkiensis* Voichyshyn, 1999, *A. verbivciensis* Voichyshyn, 1999, *Althaspis tarlovi* Voichyshyn, 2011, *Djurinaspis secunda* Voichyshyn, 2011, *Palanasaspis chekhivensis* Voichyshyn, 2011, *Pavloaspis pasternaki* Voichyshyn, 1999, *Podolaspis danieli* Voichyshyn, 2011, *Semipodolaspis slobodensis* Voichyshyn, 2011 (Class Heterostraci), “*Cephalaspis*” *djurinensis* Balabai, 1962, “C.” *microlepidota* (Balabai, 1962), *Mimetaspis concordis* Voichyshyn, 1994, *Pattenaspis rogalai* (Balabai, 1962), *Wladysagitta janvieri* Voichyshyn, 2006, *Zenaspis dzieduszyckii* Voichyshyn, 2006, *Z. kasymyri* Voichyshyn, 2011, *Z. major* (Balabai, 1962), *Z. podolica* (Balabai, 1962), *Zychaspis concinna* Voichyshyn & Solodkyi, 2004, *Z. elegans* (Balabai, 1962), *Z. granulata* Voichyshyn, 1998, and also concerning the species recognized as *nomina dubia*, “*Cephalaspis*” *feliciae* Balabai, 1962 and “C.” *sjostremi* Balabai, 1962 (Class Osteostraci) (Afanassieva and Voichyshyn 1991, Balabai 1962, Voichyshyn 1994, 1998b, 1999, 2006a, 2006b, 2011, Voichyshyn and Solodkyi 2004).

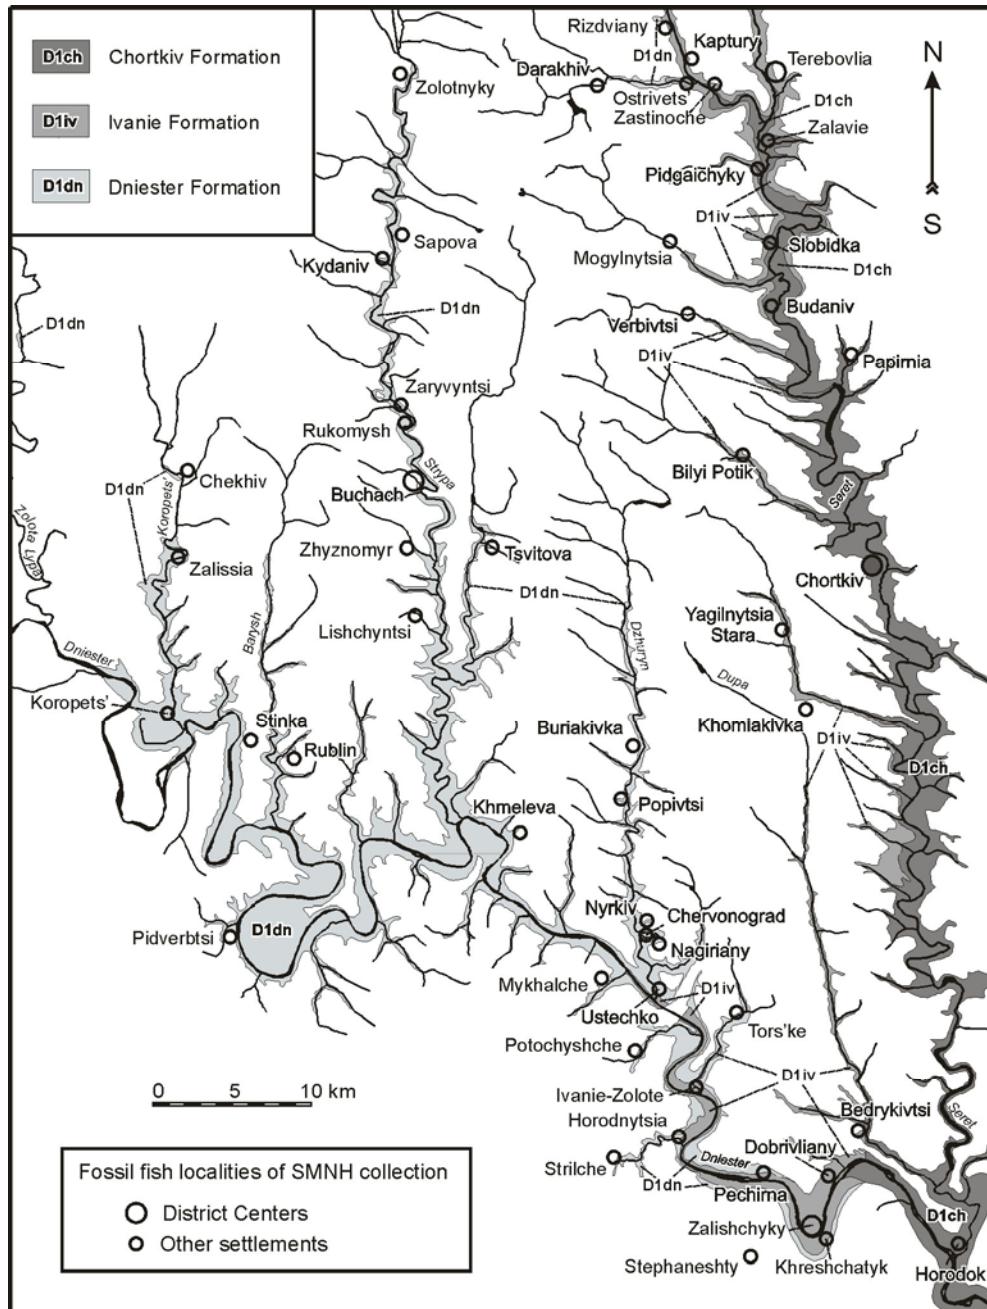

Fig.6. Lower Devonian deposits in Podolia within main area of SMNH collection origin (after Voichyshyn 2011, modified).

On the whole, the catalogue includes 1370 units of storage and 1759 fossil remains which belong to 51 species, 37 genera, 16 families, 9 orders and 5 classes of Agnatha and Pisces. Except for three specimens from Middle and Upper Devonian deposits of Holy Cross Mountains (Góry Świętokrzyskie) in Poland the entire collection are from the Lower Devonian deposits of Western Ukraine which situated in Ternopil', Ivano-Frankivs'k, Chernivtsi and L'viv Oblasts. Remains of the vertebrates have been collected at the 51 sites (localities) named after nearest (mainly rural) settlements, and from core of two boreholes (Fig. 4). In stratigraphical aspect the Ukrainian part of the collection covers a range from uppers of the Chortkiv Formation of the Tyver Group till the Strypa Stage of the Dniester Formation of Podolian Lower Devonian (Fig. 6; see Voichyshyn 2011). In time scale it corresponds with the interval between Middle Lochkovian and Middle Pragian, or approximately from 415 to 412 million years ago (see Williams et al. 2000). Specimens of the collection have been figured in 25 publications since 1957 till 2011.

The catalogue material is arranged in sequence of the register numbers. The records contain data about specimen register numbers (actual and old ones), taxonomical definition, locality and location, stratigraphical horizon, collector name, date of collecting, publication(s) with specimen figure, and specimen shortest description. The collecting date is presented in year-month-day format. The necessity of the Old Register Number presence among the record parameters stems from the fact that it was used in the publications prior to 2006.

The information part of the catalogue consists of the indexes concerning the taxonomical definition, stratigraphy unit, locality, collector and image publication. The names of Podolian localities which are relevant to the SMNH collection are provided in Ukrainian and Polish variants.

The taxonomy of the Devonian fish fauna collection above generic level and check list of the Early Devonian fishes from Podolia are added.

CATALOGUE

Majority of fossil localities is associated with nearest Podolian settlements pointed on the maps (Fig. 4, 6). Original old label notes concerning Location description are cited in quotation marks. Double Old Register Number record (for example, 17304+17317) means two specimen parts previously registered as belonged to different individuals. The lack of the record data means the shortage of the proper information (Locality and Location, Collected) or its origin absence (Old Register Number, Published Image(s)).

Voichyshyn V. Devonian Fish Fauna. – L'viv, 2015. – 307 p. (Scientific Collections of the State Museum of Natural History; Issue 5)

Abstract. The collection of Devonian fish fauna from the State Museum of Natural History NAS of Ukraine includes 1759 fossil remains which belong to 51 species, 37 genera, 16 families, 9 orders and 5 classes of Agnatha and Pisces. Except for three specimens from Middle and Upper Devonian deposits of Holy Cross Mountains in Poland the entire collection are from the Lower Devonian deposits of Western Ukraine. Remains of the vertebrates have been collected at the 51 sites and from core of two boreholes. In stratigraphical aspect the Ukrainian part of the collection covers a range from uppers of the Chortkiv Formation of the Tyver Group till the Strypa Stage of the Dniester Formation of Podolian Lower Devonian. In time scale it corresponds with the interval between Middle Lochkovian and Middle Pragian. Specimens of the collection have been figured in 25 publications since 1957 till 2011.

Войчишин В. Девонська іхтіофауна. – Львів, 2015. – 307 с. (Наукові колекції Державного природознавчого музею; Вип. 5)

Резюме. Колекція девонської іхтіофауни, яка зберігається у Державному природознавчому музеї НАН України, містить 1759 викопних решток, які належать до 51 виду, 37 родів, 16 родин, 9 рядів і 5 класів безщелепних (Agnatha) та риб (Pisces). Крім трьох екземплярів з середньо- та верхньодевонських відкладів Свентокшиських гір у Польщі, вся описана колекція походить з нижньодевонських відкладів Західної України. Викопні рештки зібрано з 51 місцезнаходження та двох свердловин. Стратиграфічно українська частина колекції охоплює діапазон від верхів чортківського горизонту тиверської серії до стрипської світи дністерської серії нижнього девону Поділля. У віковому плані це – часовий проміжок від середнього лохкова до середнього прагія. Зображення зразків колекції наводилися у 25 публікаціях з 1957 по 2011 рік.
